

# **Population Projections for Tennessee Counties and Municipalities**

**2000 — 2020**

**March 1999**

*Center for Business and Economic Research / The University of Tennessee / Knoxville, Tennessee*

# **Population Projections for Tennessee Counties and Municipalities 2000 — 2020**

---

Matthew N. Murray, Associate Director  
Center for Business and Economic Research  
and Project Director

Prepared by the  
Center for Business and Economic Research  
College of Business Administration  
The University of Tennessee, Knoxville

Prepared for  
Growth Policy Law Implementation  
Steering Committee  
Public Chapter 1101

---

March 1999

## **Contributors to the Report**

---

**Matthew Murray**, Project Director; Associate Director, Center for Business and Economic Research.

**Michael Hicks**, Visiting Research Assistant Professor and Assistant Professor of Economics

**Donald Schunk**, Graduate Research Assistant

**Patricia Hunley**, Word Processing Specialist

**Betty Vickers**, Research Associate

**Lisa Wilson**, Student Assistant

# State, County, and City Population Projections

## For the State of Tennessee

### 1. Statistical Techniques

The projections of state, county, and city population through 2020 have been generated in three stages. First, projections of population for each of Tennessee's 95 counties are produced. These county projections are then summed to obtain the state population projection. Finally, the city projections are generated by combining forecasts of each city's share of its county's population with the projected county population. The statistical techniques used to generate the county and city projections are detailed below.

#### *County Projections*

The county population projections are based on the following definition of annual population change:

$$\text{change in population} = \text{births} - \text{deaths} + \text{net migration}$$

Given this relationship, the county projections are generated by first producing projections of births, deaths, and net migration by county. From these forecasted components of population change, forecasts of the annual change in county population, and of annual total county population, are easily calculated.

The forecasts of births, deaths, and net migration are generated using a statistical model referred to as a *vector autoregression*, or *VAR*. A *VAR* is a sophisticated yet convenient statistical model used to capture the evolution of a set of related variables over time. Because it is used to model the evolution of variables over time, a *VAR* is referred to as a *time series* model. It is highly appropriate to model a set of variables using a *VAR* when it is believed that the primary force determining the values of a variable are the past values of the variable itself, as well as interactions with other related variables.

Generally, time series models such as the *VAR* have been shown to be highly effective tools for

forecasting a small set of variables over a relatively long period of time. A primary benefit of using a *VAR* to produce a forecast is that all information necessary to generate the forecast is present in the *VAR* model. That is, no external data are required to forecast from a *VAR*. An alternative approach to forecasting population would be to develop a *structural* model which attempts to fully describe all determinants of population growth. A structural model would need to include a large number of variables such as: infrastructure provision, local area income and employment, education, and so on. In other words, factors that explain fertility and death rates, and the factors that repel and attract people (i.e., net migration).

The use of such a model to accurately forecast population would entail two largely intractable steps: detailing the impacts of these variables on population growth (or its components), and developing forecasts of *each* of these variables for the purpose of forecasting population itself. Thus, forecasting population using a structural model requires first generating forecasts of every variable which has an impact on population and its component parts. These external forecasts will of course be obtained with some degree of uncertainty, compounding the uncertainty surrounding the population forecast itself. In contrast, the *VAR* does not require external forecasts, and indeed *VAR* models often produce forecasts which are superior to those produced by large structural models. The U.S. Bureau of the Census maintains both a time series and a structural model for developing forecasts of state population. They explicitly prefer the time series model, for the reasons outlined above, as well as for more technical statistical concerns.

Several statistical checks and adjustments have been performed on the forecasts of county variables to help ensure their accuracy. These adjustments are necessary in some cases because of the relatively short data history available. A short data history may lead to raw forecasts of population components which are clearly (from a statistical point of view) unreliable. If this is the case, a simple statistical adjustment is performed which produces a more reliable forecast. These statistical adjustments involve examining the births, deaths, and net migration forecasts for each county and modifying the results when necessary.

First, the forecast of births for each county is considered. If this forecast displays either an

upward or downward trend in births which is significantly different from the historical births trend, the forecast is adjusted to reflect the historical trend. This same check and adjustment is also used in the case of the county deaths forecasts. In contrast, the net migration series often does not display clear historical trends as do the births and deaths variables. To determine if the net migration forecast for a county needs to be adjusted, the final period net migration value is compared with the historical average value of net migration. If the VAR has produced a statistically unreliable forecast, these two values should be significantly different. If they are, the net migration series is adjusted by extending the historical average net migration throughout the entire forecast.

Once the population component forecasts for each county have been examined, and adjusted when necessary, the forecasted annual change in population and the resulting annual total population is calculated. Aside from the statistical checks outlined above, the county projections have been examined in light of two additional factors: population density and group quarters population. First, the projected 2020 population density for each county is compared with the county's own current population density, and with that for all of the other counties in the state. This check serves to identify counties with an unsustainable projected growth in population. Second, each county is examined for recent large changes in group quarters population, which will result in recent erratic behavior of the county's net migration series. If a county experienced an unusual change in group quarters population, such as the addition of a prison, the county's net migration series is adjusted accordingly. Therefore, the county projections are not affected by one-time changes in group quarters population.

After the county projections have been thoroughly scrutinized, they are summed to obtain the state population projection. The county population projections also serve as the foundation for the city population projections, as detailed below.

### *City Projections*

The general approach to projecting city population is to first produce forecasts of each city's

share of its respective county's total population. Given these forecasted shares, and the previously generated county population projections, the city population projections are easily calculated. More specifically, the forecasts of city population shares have in most cases been produced by extrapolating the historical trend of the city population share.

Efforts were made to ensure that the city population projections take into account recent annexations and other recent sources of city population change. This is accomplished by comparing the city's 1998 certified population with the Census Bureau population estimate for 1996. If the 1998 population is higher than the 1996 estimate, the city's population forecast is adjusted upward to reflect the higher level of population. For those cities which had zero population through 1996, the population projection is generated by extending the 1998 city population share which is based on the 1998 certified population.

A consistent adjustment was made for cities whose population declined after 1990, and for which the projection was for a continued decrease. In light of the relatively short series of historical city-level data available, it is difficult to justify projecting a continued fall in the population of these declining cities through 2020. Therefore, in these cases the city's population is projected to be at least at its 1990 level throughout the entire forecast.

The use of city-specific historical data ensures a reliable relationship between the city and county growth patterns. However, this relatively short data series does not automatically ensure consistency with longer-term settlement patterns in terms of the mix of urban and rural population. For the state as a whole, in 1970 and 1980 approximately 60 percent of the total population was accounted for by incorporated areas. While this percentage slipped slightly to 58.8 percent in 1990, the long-term historical state-level data suggests that a reliable projection of population should have between 58 and 60 percent of total population in incorporated areas. Indeed, the city population projections do indicate that the percent of people living in incorporated areas is consistent with the long-term trend. In the year 2000, the projections indicate a 58.8 percent incorporated population. By 2020, this figure rises slightly to 59.2 percent.

Thus, the county and city population projections are completely consistent with historical

settlement patterns for the state as a whole. However, this alone does not ensure that the projections for *any one* county are consistent with historical settlement trends *within* that county. Therefore, the projected urban-rural mix *for each individual county* was examined in light of the settlement patterns in that county between 1960 and 1996. This final check strongly indicates that the split between incorporated and unincorporated areas, as implied by the population projections, is entirely consistent with historical trends both as a statewide average and at the individual county-level.

## **2. Data Sources**

### *County Projections*

The 1970, 1980 and 1990 Decennial Censuses of Population, collected and published by the Bureau of the Census, U.S. Department of Commerce, provide the core data for the county projections. Estimates for intercensal years, 1971-1979, 1981-1989, and 1991-1997, were also produced and published by the Population Division of the Census Bureau.

The components of change—births, deaths, and net migration—are detailed on the Census Bureau web site for the years 1980-1996. These data were used as reported with the exception that 1980 births and deaths were adjusted to equal a 12-month period (July 1980-June 1981) rather than a 15-month period (April 1980-June 1981).

Data on births and deaths for 1970-1980 are not available from the Census Bureau. For these years, details of births and deaths by county of residence are those reported annually in *Tennessee Vital Statistics* by the Tennessee Department of Health. Also, net migration data for 1970-1980 were computed by the Center for Business and Economic Research as a residual of the later year's population less the earlier year's population adjusted for natural increase (births minus deaths).

Information on persons living in Group Quarters from 1990 to 1997 are also from the Census Bureau. Prison populations, as well as prison capacities, are detailed in the *Annual Report*, Tennessee Department of Corrections.

Finally, measures of population density incorporate the area measurements for counties as reported in the 1990 Census of Population.

### *City Projections*

The 1990 Census counts, and Census estimates for 1991-1996, are the core data for the city population projections. These data are from the Bureau of the Census, U.S. Department of Commerce, and can be found on the Census Bureau web site. These data were supplemented by information on annexations and special censuses from the “*1998 Certified Population of Tennessee Counties*” compiled by the Tennessee Department of Economic and Community Development, Local Planning Assistance Office.
